Water Quality Monitoring – Streams

Stream Monitoring

Water quality information collected by the Stream Monitoring Program is needed to help determine compliance with MN water quality standards, to determine the extent of nonpoint source pollution, to help with the development of TMDL (Total Maximum Daily Load) plans, and to measure progress toward achievement of water quality standards as BMPs are implemented.

Currently, there are twenty-four automated stream monitoring stations located around the Twin Cities.

Why the Metropolitan Council?

The MCES Stream Monitoring Program was initiated in the late 1980s. Point source pollution controls alone were insufficient to attain the water quality goals of the Federal Clean Water Act.

Since then, the stream monitoring program has grown for several reasons:

- It is relevant to the Metropolitan Council’s regional planning and modeling efforts.
- It promotes local resource stewardship and decision making.
- It is mandated by state law (MN Statute 473.157) to establish target pollutant loads for each watershed.

The stream monitoring Quality Assurance Program Plan (PDF) (updated 1/11) provides a detailed description of the program’s purpose, procedures, methods and quality assurance objectives.
Station Locations

Stream monitoring stations are located near watershed outlets to effectively measure the mass, or non-point source pollutant “load”, that the tributary streams transport to the major rivers (Minnesota, Mississippi, and St. Croix).

Key rivers, streams, creeks and ditches are sampled during significant runoff events and during base flow conditions to help determine the sources and extent of non-point sources of pollution.

Water Quality Variables Analyzed

Metropolitan Council Environmental Services monitors streams in the Twin Cities Metro Area and Mankato Area for a variety of water quality variables (listed on the right). These variables are not always analyzed at all sites all of the time. The variables and sample frequency depends on the sample condition and water quality concern.

Sample Collection

Stream samples are collected on a regular basis during base flow conditions. In the winter, monthly grab samples are obtained. In the spring, summer and fall, sample frequency increases to twice a month. Depending on specific site conditions, additional grab samples might be taken to help further characterize water quality. Along with these base flow grab samples, composite samples are collected by the automatic samplers during storm runoff events. Samples are collected by the automatic sampler on an equal-flow increment (EFI) basis. With EFI sampling, composite samples are collected throughout the event, with discrete sub-samples representing equal volumes of flow.

The photo above shows Equal Flow Increment samples collected from the Le Sueur River in June 2001. The two jars are poured into the bigger plastic jug, to create a "composite" sample. From the big plastic jug, the composite samples are poured into labeled lab bottles. These sample bottles are then transported to the MCES analytical laboratory, which conducts water chemistry analysis on all stream monitoring samples obtained (grab samples and event composite samples).
